THE LITTLE GRAVE.

There's a spot on the hillside far away,
Where in summer the grass grows green;
Where, beneath a rustling elm tree's shade,
A moss-covered stone is seen.
It's a quiet and unrequited spot,
A solitude lone and wild.
Yes, somebody's hopes are buried there—
The grave of a little child.

In winter, alas! that mossy stone
Is hid 'neath a shroud of snow;
But around it, in springtime, fresh and sweet,
The daisies and violets grow.
And o'er it the summer breezes blow,
With a fragrance soft and mild.
And the autumn's dew leaves thickly strewn
That grave of a little child.

And every year there's a redoubt comes,
When the month of May is nigh,
And builds her nest in this quiet spot,
Mid the elm tree's branches high.
With her melody sweet and low she thrills,
As if by the scene beguiled;
Perhaps—who knows? 'tis an angel come
To the grave of that little child.

Yes, somebody's hopes are buried there,
For, though years may come and years may go,
'Twill never come back again.
Yet blessed are those who die in youth,
The pure and the undecayed;
Some road to Heaven, perchance, runs through
That grave of a little child.

ANIMALS AND SOIL.

The Wonderful and Useful Work Done by Ants.

What Is Accomplished by Crickets, Field Mice, Bugs, Etc.—But the Ants, in Many Districts, Are the Most Important Agents.

The admirable studies of Mr. Darwin on the influence of the earth-worms upon the soil has made it clear that these animals exercise a most important effect in its preparation for the use of plants. Mr. Darwin's luminous essay has served to call attention to the effect of organic life on the development of the soil-coating. In the following pages I propose to submit the results of some studies of a general nature, which serve to show that a number of other animals have a considerable influence on the preparation of soils.

Our soils, as is well known, depend upon a variety of actions which serve to break up the rocky matter of the earth and to commingle that matter with organic materials more rapidly than the erosive agents can remove the debris from the point at or near which it decays. For the formation of the soil two actions at least are essential. First, the bed-rock must be broken into fragments sufficiently separated from each other to permit the passage of roots between them; second, the rock fragments must be still further comminuted and commingled with organic waste to make the combination of organic and inorganic matter on which the utility of the soil absolutely depends. Although the earth-worms are undoubtedly very important agents in overturning and breaking up of soil, it appears to me that they are most effective in the tilled fields or in the natural and artificial grass-lands. So far as I have been able to observe, these creatures are rarely found in our ordinary forests where a thick layer of leaf-mold, commingled with branches, lies upon the earth. The character of this deposit is such that the creatures are not competent to make their way through it, and they therefore in the main avoid such situations. Moreover, wherever the soil is of a very sandy nature, earth-worms are scarcely found if they are present at all. These worms are practically limited to the soils of a somewhat clayey character, which have no coating of decayed vegetation upon them.

As the greater portion of the existing soil has been produced in forest regions, I shall first examine the action of various animals upon the soils of wooded countries. The mammals are, of all our vertebrates, the most effective in their action upon the soil of forests. Twenty species, or more, of our American mammals are burrowers in the forest bed. They either make their habitations beneath the ground or resort to it in the pursuit of food. Of these our burrowing rodents are perhaps the most effective, but a large number of other small mammals resort to the earth and make considerable excavations. In forming their burrows, or in the pursuit of other burrowing animals, these creatures often penetrate through the whole or greater portion of the soil-covering. The material which is withdrawn from the burrow is accumulated about its mouth. The result is the overturning of a considerable amount of the earth and a consequent commingling of the material with vegetable matter. When brought to the surface and left exposed to the action of frost the breaking up of the material is greatly favored, and thus the formation of the soil is facilitated.

Considerable as is the effect of burrowing mammals, the principal overturning of the earth in our primeval forests is accomplished by the invertebrate animals. Where the woods are not very dense, and particularly where the soil is somewhat sandy, our largest species of ants are very effective agents in working over the soil. Their burrows extend to the depth of some feet below the surface, and each hill brings to the air several cubic feet of excavated matter, which, as slight inspection shows, is much commingled with vegetable matter. Wherever these ant-hills abound they commonly exist to the number of a score or more on each acre, and the occupants of each hill, in many cases, bring as much as a cubic foot of matter to the surface in the course of a single year. The action of rain constantly operates to diffuse this material on every side of the hill. We may often observe a thin layer of sediment extending for a considerable distance from the elevation.

As is well known to all those who have inspected the soil within virgin forests, the earth is occupied by a host of larval insects, principally belonging to the group of beetles, but including also many orthopterous insects. These creatures in the course of their life underground displace a good deal of soil, a portion of which is thrown upon the

surface, the greater part, however, being merely dislodged beneath the surface. The effect, however, is to commingle and to break up the soil, and thus favor its commination. Although the roots of trees do by far the larger part of the rearing which is accomplished in the soil layer, they do not bring about much commingling of the soil. The thrusts which they apply to shear the materials about, and so to a certain extent mix them, but by far the larger part of the commingling is effected by the animal life which dwells beneath the forest bed.

Where the woods are wet and favor the development of the crayfish the effect of this group of animals on the overturning of the soil is extremely great. It probably exceeds that which is accomplished in our ordinary fields by the action of the earth-worms. A single crayfish will often bring in the course of a single season's activity not less than half a cubic foot of earthy matter to the surface. In certain districts where these animals abound there appear to be not less than a thousand to each acre of surface. If such be their number, it is evident that not less than five hundred cubic feet of matter is brought to the surface from a considerable depth in the course of a year. As this matter is generally of a rather fine nature and easily dissolved in water, it rapidly washes away and forms a thin sheet on the surface. I am inclined to believe that large areas of our wet woods and the open border lands along our streams are completely overturned to the depth of two feet or more in the course of half a century by the actions of these animals. It is not impossible, indeed, that the very fine division of the soil which characterizes the regions inhabited by these creatures may be in good part due to their action. In this manner the creatures may have in part worked to bring about the very conditions which best serve their needs. "In open grounds, in natural prairies or grass-plains, the smaller species of ants are extremely effective agents in overturning the spoils. Wherever the ground remains for some time unplowed, it becomes occupied by these creatures. In the sandy soils of Eastern Massachusetts, the overturning accomplished by these creatures assumes a geological importance. For many years I have been puzzled by the fact that the glacial terraces and plains of this region were extensively covered to the depth of a foot or more by a coating of fine sand and very small pebbles, while below the depth of a foot pebbles of larger size are very numerous and the spaces between them but imperfectly occupied with any material. It is obviously impossible to explain these conditions through the action of earth-worms, for the reason that these creatures are rarely found in soils of this description. From much observation I have become convinced that this coating of sandy material is to a great extent to be explained by the action of various species of ants, in the forest condition by the work of the larger black ants, and in the condition of open plains by that of the smaller species.

The amount of material which these creatures bring to the surface in a single season is surprising. At several points in Eastern Massachusetts I have found the surface to contain at least one ant-hill to each square foot of area, or about forty thousand hills to the acre. This is probably an exceptionally great number; it will perhaps be safer to estimate the number at twenty thousand to the acre. The incoherent heaps of excavated matters which these creatures form are quickly washed away by the rain, or in many cases are blown away by strong winds, and so scattered over the surface. As soon as destroyed they are, in most cases, rebuilt, the result being that a single hill is reconstructed at least half a dozen times during the season. I have estimated that the amount of material brought to the surface often exceeds three cubic inches to each square foot of surface in a single year, or about a fifth of an inch of the whole area each year. Thus, in the term of fifty years, the accumulation of material on the surface would amount to as much as an inch and, reckoning the soil as having an average depth of one foot, a total overturning would be accomplished in less than one thousand years. It is likely that in some cases, over considerable areas, a tolerably complete overturning is brought about in less than a quarter of this time.

The effect of this action of ants on the soil material is peculiar. The tendency is like that noted by Dr. Darwin in the case of earth-worms to bring the finer particles to the surface. I am inclined to think the ants accomplished this part of their work even more effectively than the earth-worms, for the reason that they penetrate more deeply between the stones than their less active associates. Like the earth-worms, but in larger measure, the ants convey considerable amounts of organic matter into the soil. Their winter store of food is deeply buried, and much of it remains unconsumed in the nether earth. There is thus a constant imbuing of vegetable matter beneath the materials which they bring to the surface.

Although the burrowing vertebrates operate most vigorously in the forest-covered regions, they also exercise a certain influence on the open country. The moles, which work only here and there in the forest, are conspicuous agents in overturning the soil in the grassed regions. Still, as this group is peculiarly limited in its distribution and rarely penetrates to more than four or five inches below the surface, it exercises a relatively small effect. The field-mice are more potent agents in effecting the character of the soil. Their dwelling-chambers are at a considerable depth below the surface, and in forming them, they bring a certain amount of matter to the open air. Moreover, the remains of their food, as well as their excrements, are important contributions to the organic matter of the soil. Insects in their larval stage exercise a less effect in the open field than in the forest-covered regions; still they are not to be left out of account in considering the process of soil-making in such areas. In Europe the rabbit, which has a habit of burrowing to a considerable depth, and in certain dis-

tricts west of the Mississippi, the prairie dogs overturn the soil on the areas they occupy with considerable rapidity. Still the number of these creatures in any given district is not great, their influence is mostly exercised in a very local way.

The foregoing considerations make it tolerably clear that our ants are, in some districts, by far the most important agents in overturning the soil and in commingling the superficial organic matter with the mineral material of which it is composed. Although on a field of a certain class, those which are of a clayey nature, the earth-worms are probably more efficient soil-makers than the ants, this latter group appears to be, at least in the eastern part of North America, on the whole, by far the most effective in the preparation of the soil for the needs of plants. They do not, it is true, take the soil into their bodies, and thus disintegrate it, as the earth-worms do, but they accomplish what is perhaps the more important task of rapidly overturning the soil-material, as well within the forests as in the open fields, wherever that material is of a sandy nature.—*Popular Science Monthly.*

WAS ACCOMMODATING.

A Genuine Tennessee Mountain After-Dinner Appetizer.

A weary traveler stopped at a wayside clapboard store, among the East Tennessee mountains, and addressing an old fellow who nodded at him, said: "My dear sir, I am exceedingly hungry, having ridden all day without any thing to eat. What have you got?"

"Wall, I dunno. Ain't took stock lately."

"Got some cheese, havn't you?"

"Did have some, finest you ever seed, but the rats got a foul ur hit."

"You surely have crackers?"

"Did have 'bout er ha'fer box ov about the finest crackers in this yer country, but my ole hen got ter lay in the box, an' now she's a-settin' on the eggs an' has got sich a good start that I don't want ter interfere with her."

"Very singular."

"Don't know that it is, fur I've kep' 'sto' for er good while, an' I have noticed that a hen would rather git in a box an' lay on the crackers than putty nigh anywhere else. Seems like she kin lay better. 'Pears ter be suthin' erbout the crackers that inspires her."

"You have some dried herrings, I suppose."

"Yes, some of the finest I ever seed, but you see, the cat has got in the habit of draggin' 'em over the flo' at night. She chaws a little bit on one an' then on another, an' has made some of 'em look sorter wasted, still, if you think you ken find one that's above suspicion, w'y, go 'round that an' he'p yo'self."

"I don't care to take any chances."

"Jest ez well not, I reckon, fur the flo' ain't so mighty clean an' I'm putty sartin' that she's drag the most ov them fish around even if she hain't nibbled at 'em much."

"Have you got any fresh eggs?"

"Wall, I did have some ov the freshest I ever seed, but I wouldn't like to risk 'em now."

"Great goodness, can't you give me something?"

"That's a middlin' ur meat over thar. You might cut you off a few slices and brile 'em here on the coals."

"I thank you for the suggestion."

The traveler cut off several slices of meat and soon had them broiled. After satisfying his hunger, he said:

"I don't know what I should have done had it not been for that bacon."

"Comes in mighty handy when a feller's sorter hungry."

"Yes, and although I have eaten many a better meal I must say that I never enjoyed one more. How much do I owe you?"

"Nothin' a tall."

"You are surely very accommodat-

ing, but you can not afford such liber-

ality."

"O, yas, in this case I could, fur you see the meat wain't no use ter me. Old Bill Hinsley's dog drag it outen the smokehouse tuther day an' wuz draggin' it 'cross a field, when one ov the boys made him drap it. The meat was foteh back ter me an' ez the dog went mad the next day I was sorter 'ferd ter eat—w'y, I'm sorry you 'pear ter be snatched, stranger. Wall, goodbye. When you air passin', drap in."

—*Arkansas Traveler.*

REVENGE IS SWEET.

How a Counter Gentleman and Saleslady Rebuked Their Employer.

The cold, haughty, purse-proud merchant prince who treats his ribbon counter gentleman and gentlemen's underwear salesladies with mere civility or chilling indifference had better beware. The time may come when their positions may be reversed.

"See here, Jinks," said one of these arrogant millionaires one day to a ninety-pound ribbon counter clerk, "you want to attend to your business better, young man, and not waste so much of your time flitting with that red-headed underwear girl across the aisle, mind that."

Enraged and humiliated, the downtrodden ribbon counter serv' vows and seeks revenge. His time comes soon, aye, that very night!

The purse-proud, cold-blooded merchant prince goes to the theater. He buys an admission ticket and stands up, being of an economical turn of mind.

"Let us pass, sir," says a calm, cold voice at his side. He looks down and beholds the ribbon-counter clerk in the magnificence of full dress, with the underwear girl in flowing robes and sixteen-button kids hanging to his arm. The eyes of the men meet, but there is no sign of recognition on the part of the ribbon-counter clerk, only a cold, haughty, fixed stare as he passes proudly on to the three-dollar seats reserved for him and the underwear girl, while the snubbed and humiliated merchant prince stands on in the midst of his own bitter reflections.—*Detroit Free Press.*

—Cavendish in 1766 discovered hydrogen; and between 1774 and 1779 Priestley discovered oxygen, azote and nitrous gas.

It is said that among the murderers hanged during the past three years the name of John led all others by a large majority. And it may be added that it was a John, first name Demi, that was mainly instrumental in making murderers of possibly every one of the entire lot.—*Boston Transcript.*

A GIRL'S INVENTION.

How a Veteran's Daughter is Filling a Depleted Family Treasury.

In a remote but decent part of Boston has lived for about fifteen years an English family of rather unique interest. The father served in the war of the rebellion, and, being a partial invalid in consequence, receives a small pension, which does not go far toward supporting the family, and he can do little besides draw his pension and suffer his constant pain. The mother is a small woman, with large brown eyes and pale cheeks. She has had a toilsome life, indeed, and has done all sorts of work to try and eke out the family support. Two daughters, the elder somewhat noted in her neighborhood as a beauty, and a small boy make up the balance of the household. Although desperately poor, the family have been as proud as Lucifer and seemed bound to accept no more charity than was absolutely unavoidable, though there are plenty of well-to-do people around them who would gladly have contributed to their aid, as every member of the family commanded respect. They have come to be known even outside their narrow circle from their constant effort to better themselves, trying now this thing and now that. Every thing failed until a short time ago; but at last the family have struck something that will give them ease and comfort if not comparative wealth. The handsomest daughter is credited with the discovery, which is simply a new method of treating photographs in reproduction. Her name has been given to it, and her work is getting more and more circulated every day with of course an increased inflow of dollars to the family treasury. She has secured a patent on her process. All the photographers are puzzled by the work and would like to have it for use in their business, as they see that this girl is getting as many orders as she can fill at the good price of three dollars for each cabinet reproduction. The pictures are the same size as the cabinet photographs, but softer and more pleasing in tone, and are mounted under thick plate-glass with beveled edges. How she makes her copies nobody has been able to find out as yet, but in the slang of the day her work "goes."—*Springfield Republican.*

Not so Much of a Success.

"Yes," said a business man, "Singletan has been wonderfully successful, not particularly on account of any shrewdness but because he is such a close collector. He is undoubtedly the best collector in this city."

"I have heard so," some fellow remarked, "and I used to believe it, but I have found that he is not such a successful collector after all."

"How so?"

"Well, you see, I have owed him a bill for quite awhile and he never has succeeded in collecting it."—*Arkansas Traveler.*

SCIENCE AND INDUSTRY.

New silk mills are springing up everywhere, and the immigration of foreign weavers has almost stopped.

Never in one season was there such a demand for oak to go into house finishing and furniture as the present. Red and white oaks are particularly wanted.

A new attachment to the microscope has been devised, the object of which is to observe the melting points of minerals while under the process of examination.

It is estimated that the sum spent on new buildings in this country last year was \$2,600,000,000, and that the transfers of real estate amounted to \$10,000,000,000.

Careful experiments have shown that waste silk is the most effective of all non-conducting coverings for steam-pipes, and the demand for this purpose is great in spite of the cost.

The values of the exports of mineral oils from the United States for the year ended December 31, 1887, showed a decrease of \$2,584,977 from the values of the corresponding period of 1886.

The process of manufacturing gas from water at Los Angeles, Cal., is a magnificent success. Its bright, steady light has been pronounced a decided improvement over electricity.

A simple formula for the preparation of hektograph ink is given by a competent authority. Take one part of aniline, of the color desired, dissolve in about seven parts of water, and add one part of glycerine.

Meteorites sometimes attain a velocity of 180,000 feet per second. When passing through the air at this rate the friction is so great that the air is heated up to a temperature of 10,800 degrees Fahrenheit.

The French national printing office employs girls as type-founders, printers, book-sewers, book-binders, etc., the wages ranging from fifty cents to one dollar per day. After thirty years' service both men and women are retired upon a pension.

As a wood preservative naphthalene is now largely used in Scotland, its action being to destroy all albuminoid compounds in the wood, leaving it dry and clean to handle, and with only a faint, aromatic smell. The naphthalene is melted in a vessel capable of being tightly sealed, and in this the wood is saturated.

Extensive use is now being made in France of the unique article known as wood wool, consisting of extremely thin and slender shavings of wood, that are comparable to paper cut for packing. It weighs some forty or fifty per cent. less than the materials generally used for such a purpose, and its beautiful appearance, fineness, and exceeding cleanness have brought it into great favor.

A recent chemical examination of several prominent brands of "family lard" showed them to be variously constituted of different ingredients, and in one case not a trace of real lard could be found in the sample analyzed.

A prominent lard manufacturer testified before the Senate Committee on Agriculture, at Washington, that so far as he knew the lard thus manufactured is more popular with the people than the genuine article is.

BANKING IN CHINA.

How Pigtails Tellers Handle Scraps of Silver and Clumsy Bank Notes.

A curious place that we looked into on our way across the city of Canton was a Chinese bank, where the counterpart of the brisk young cashiers, tellers and accountants of our home banks were sitting in pig-tails, and the long blue blouses of gentlemen and scholars, shoveling silver Mexicans from basket to basket, and letting them fall on the stone floor with a deafening ring and clatter. A Chinaman can do nothing quietly, and noise is his necessary accompaniment to every action. Every one of the pewtery-looking dollars is weighed and stamped by the bank, rung on stone slabs and fully tested, and there are baskets full of fragments, halves and chips of silver dollars that pass as smaller coins. These scraps and bits of silver pass current by their weight and their purity is tested by the ring. The Hong Kong and Shanghai Banking corporation issue paper notes of different values that save one from carrying loads of these clumsy Mexican dollars about with one, but the bank notes are as clumsy in proportion. They are all over six inches long and four inches wide, of a tough, fibrous paper, as thick as blotting paper, and as flabby as so much dirty calico, which they chiefly resemble. Those diploma-sized notes of the Bank of England are small and compact by comparison, and every common-sense traveler craves for Mitkiewicz and his syndicate to come with the great bank and do away with the ugly Mexican and the clumsy English notes. A great proportion of Chinese talent must be employed in counterfeiting Chinese dollars, to judge from the numbers about and the wariness with which every one accepts one of the coins. A most clever counterfeit passed off on me was one that was plainly pure silver and newly minted. An expert rapped it sharply with his pen-knife, and the top fell off like the lid of a box, and disclosed an interior of pure pewter filling in the shell of silver. At the American schedule of wages, two dollars of a silversmith's time had been used to plane off in a thin shaving the top of the dollar, dig out the solid part and fill up the cavity with lead, and bring the deceptive seventy-cent dollar down to a silver value at ten cents or less.—*Cor. St. Louis Globe-Democrat.*

Question From the Jury.

"Gentlemen of the jury," said the judge, as he concluded his charge, "if the evidence shows in your minds that pneumonia, even indirectly, was the cause of the man's death, the prisoner can not be convicted."

An hour later a messenger came from the jury room.

"The gentlemen of the jury, your Honor," he said, "desire information."

"On what point of evidence?"

"None, your Honor; they want to know how to spell pneumonia."—*N. Y. Sun.*

\$100,000 - IMPORTANT - \$100,000 TO MANUFACTURERS.

The ABILENE IMPROVEMENT CO. offers \$100,000 IN BONUSES

to reliable manufacturing concerns who will locate in Abilene. Abilene is the largest as well as the most prosperous city in Central Kansas. It will soon have

THREE NEW TRUNK LINES OF RAILROADS, making FOUR lines, which will insure unequalled shipping facilities.
